

Package "hopit"

February 20, 2019

anova.hopit	<i>Likelihood Ratio Test Tables</i>
-------------	-------------------------------------

Description

Compute likelihood ratio test for two or more hopit objects.

Usage

```
## S3 method for class 'hopit'  
anova(object, ..., method = c("sequential",  
  "with.most.complex", 'with.least.complex'),  
  direction = c("decreasing", "increasing"))
```

Arguments

object	an object containing the results returned by a hopit.
...	additional objects of the same type.
method	the method of model comparison. Choose "sequential" for 1-2, 2-3, 3-4, ... comparisons or "with.most.complex" for 1-2, 1-3, 1-4, ... comparisons, where 1 is the most complex model.
direction	determine if complexity of listed models is "increasing" or "decreasing" (default).

Value

a vector or a matrix with results of the test(s).

Examples

```
# DATA
data(healthsurvey)

# the order of response levels is decreasing (from the best health to
# the worst health)
levels(healthsurvey$health)

# Example 1 -----

# fitting two nested models
model1 <- hopit(latent.formula = health ~ hypertension + high_cholesterol +
  heart_attack_or_stroke + poor_mobility + very_poor_grip +
  depression + respiratory_problems +
  IADL_problems + obese + diabetes + other_diseases,
  thresh.formula = ~ sex + ageclass + country,
  decreasing.levels = TRUE,
  control = list(trace = FALSE),
  data = healthsurvey)

# model with interaction between hypertension and high_cholesterol
model2 <- hopit(latent.formula = health ~ hypertension * high_cholesterol +
  heart_attack_or_stroke + poor_mobility + very_poor_grip +
  depression + respiratory_problems +
  IADL_problems + obese + diabetes + other_diseases,
  thresh.formula = ~ sex + ageclass + country,
  decreasing.levels = TRUE,
  control = list(trace = FALSE),
  data = healthsurvey)

# Likelihood ratio test
lrt1 <- anova(model1, model2)
lrt1

# print results in shorter form
print(lrt1, short = TRUE)

# equivalently
lrt.hopit(model2, model1)

# Example 2 -----

# fitting additional nested models
model3 <- hopit(latent.formula = health ~ hypertension * high_cholesterol +
  heart_attack_or_stroke + poor_mobility + very_poor_grip +
  depression + respiratory_problems +
  IADL_problems + obese * diabetes + other_diseases,
  thresh.formula = ~ sex + ageclass + country,
  decreasing.levels = TRUE,
  control = list(trace = FALSE),
  data = healthsurvey)
```

```

model4 <- hopit(latent.formula = health ~ hypertension * high_cholesterol +
               heart_attack_or_stroke + poor_mobility + very_poor_grip +
               depression + respiratory_problems +
               IADL_problems + obese * diabetes + other_diseases,
               thresh.formula = ~ sex * ageclass + country,
               decreasing.levels = TRUE,
               control = list(trace = FALSE),
               data = healthsurvey)

# sequential likelihood ratio tests
# model complexity increases so direction = "increasing"
anova(model1, model2, model3, model4,
       direction = "increasing", method = "sequential")

# likelihood ratio tests of the most complex model with the rest
anova(model1, model2, model3, model4,
       direction = "increasing", method = "with.most.complex")

# likelihood ratio tests of the least complex model with the rest
anova(model1, model2, model3, model4,
       direction = "increasing", method = "with.least.complex")

```

boot_hopit

Bootstrapping hopit model

Description

boot_hopit performs bootstrap of a function dependent on fitted model. In each of the bootstrap repetitions a set of new model coefficients is drawn from the multivariate normal distribution, assuming originally estimated model coefficients (see [coef.hopit](#)) as a mean and using model variance-covariance matrix (see [vcov.hopit](#)). The drawn coefficients are then used to calculate the measure of interest using a function delivered by func parameter.

Usage

```

boot_hopit(model, data, func, nboot = 500, unlist = TRUE,
           boot.only.latent = TRUE, robust.vcov = TRUE, ...)

```

Arguments

model	a fitted hopit model.
data	data used to fit the model.
func	function to be bootstrapped of the form func(model, data, ...).
nboot	number of bootstrap replicates.
unlist	logical indicating if to unlist boot object.
boot.only.latent	logical indicating if to perform the bootstrap only on latent variables.
robust.vcov	see vcov.hopit .
...	other parameters passed to the func.

Value

a list with bootstrapped elements.

```

getCutPoints	<i>Calculate threshold cut-points and individual adjusted responses using Jorges' method</i>
--------------	--

Description

Calculate threshold cut-points and individual adjusted responses using Jorges' method

Usage

```

getCutPoints(model, subset = NULL, plotf = TRUE, mar = c(4, 4, 1, 1),
             oma = c(0, 0, 0, 0), XLab = "Health index", XLab.cex = 1.1,
             YLab = "Counts", YLab.cex = 1.1, decreasing.levels = TRUE,
             group.labels.type = c("middle", "border", "none"))

```

Arguments

model	a fitted hopit model.
subset	an optional vector specifying a subset of observations.
plotf	a logical indicating if to plot the results.
mar, oma	see par .
XLab, XLab.cex	label and size of the label for x axis.
YLab, YLab.cex	label and size of the label for y axis.
decreasing.levels	logical indicating if self-reported health classes are ordered in decreasing order.
group.labels.type	position of the legend. One of middle, border, or none.

Value

a list with following components:

<code>cutpoints</code>	cutpoints for adjusted categorical response levels with corresponding percentiles of latent index.
<code>adjusted.levels</code>	adjusted categorical response levels for each individual.

getLevels

Summarize adjusted and original self-rated response levels

Description

Summarize adjusted and original self-rated response levels.

Usage

```
getLevels(model, formula = model$thresh.formula,
  data = environment(model$thresh.formula), decreasing.levels = TRUE,
  sort.flag = FALSE, plotf = TRUE, sep = "_", mar = c(7, 2, 1.5,
  0.5), oma = c(0, 3, 0, 0), YLab = "Fraction [%]", YLab.cex = 1.1,
  legbg = grDevices::adjustcolor("white", alpha.f = 0.4), legbty = "o")
```

Arguments

model	a fitted hopit model.
formula	a formula containing the grouping variables. It is by default set to thresh-old formula.
data	data used to fit the model.
decreasing.levels	logical indicating if self-reported health classes are ordered in increasing order.
sort.flag	logical indicating if to sort the levels.
plotf	a logical indicating if to plot the results.
sep	separator for levels names.
mar, oma	see par .
YLab, YLab.cex	label and size of the label for y axis.
legbg	legend background color. See bg parameter in legend .
legbty	legend box type. See bty parameter in legend .

Value

a list with following components:

original	frequencies of original response levels for selected groups/categories.
adjusted	frequencies of adjusted response levels (Jurges 2007 method) for selected groups/categories.
N.original	numbers of original response levels for selected groups/categories.
N.adjusted	numbers of adjusted response levels (Jurges 2007 method) for selected groups/categories.

categories	selected groups/categories used in summary.
tab	original vs. adjusted contingency table.
mat	a matrix with columns: grouping variables, original response levels, adjusted response levels. Each row corresponds to a single individual from the data used to fit the model.

healthsurvey*Artificially generated health survey data*

Description

A dataset containing artificially generated survey data

Usage

healthsurvey

Format

A data frame with 10000 rows and 11 variables:

ID personal identification number.**health** reported health, 5 levels.**diabetes** has diabetes? "yes" or "no"?**obese** has obese? "yes" or "no"?**IADL_problems** problems in Instrumental Activities of Daily Living? "yes" or "no"?**hypertension** has hypertension? "yes" or "no"?**high_cholesterol** has high cholesterol? "yes" or "no"?**respiratory_problems** has respirator problems? "yes" or "no"?**heart_attack_or_stroke** had stroke or heart attack? "yes" or "no"?**poor_mobility** has poor mobility? "yes" or "no"?

very_poor_grip cannot perform grip strength? "yes" or "no"?

depression has depression? "yes" or "no"?

other_diseases has other diseases? "yes" or "no"?

sex sex/gender: woman or man.

ageclass categorized age: [50,60), [60,70), [70,80), [80,120).

education two levels of education: primary or lower and secondary or higher.

country country: X, Y, or Z.

csw cross-sectional survey weights.

psu primary statistical unit.

Source

Data was randomly generated using probabilities of occurrence of particular combination of diseases, conditions, sex, age, education, reported health, etc. The structure of the data and some probabilities were inspired by WAVE1 SHARE database (DOIs: 10.6103/SHARE.w1.600), see Börsch-Supan et al for methodological details (Börsch-Supan et al. 2013).

The SHARE data collection has been primarily funded by the European Commission through FP5 (QLK6-CT-2001-00360), FP6 (SHARE-I3: RII-CT-2006-062193, COMPARE: CIT5-CT-2005-028857, SHARELIFE: CIT4-CT-2006-028812) and FP7 (SHARE-PREP: N°211909, SHARE-LEAP: N°227822, SHARE M4: N°261982). Additional funding from the German Ministry of Education and Research, the Max Planck Society for the Advancement of Science, the U.S. National Institute on Aging (U01_AG09740-13S2, P01_AG005842, P01_AG08291, P30_AG12815, R21_AG025169, Y1-AG-4553-01, IAG_BSR06-11, OGHA_04-064, HHSN271201300071C) and from various national funding sources is gratefully acknowledged (see www.share-project.org).

None of the individuals (records) represent any true individual (record) of the SHARE database

print(t(healthsurvey[1:6,-1]), quote=FALSE, na.print='NA', right=TRUE)
```

hopit.control

*Auxiliary for controlling the fitting of hopit model***Description**

Auxiliary function for controlling the fitting of hopit model. Use this function to set control parameters of the [hopit](#) and other related functions.

Usage

```
hopit.control(grad.eps = 3e-05, bgfs.maxit = 10000, cg.maxit = 10000,
  nlm.maxit = 150, bgfs.reltol = 5e-10, cg.reltol = 5e-10,
  nlm.gradtol = 1e-07, nlm.steptol = 1e-07, fit.methods = "BFGS",
  quick.fit = TRUE, trace = TRUE, transform.latent = "none",
  transform.thresh = "none")
```

Arguments

grad.eps	epsilon for numerical Hessian function.
bgfs.maxit, cg.maxit, nlm.maxit	the maximum number of iterations. See optim and nlm for details.
bgfs.reltol, cg.reltol	relative convergence tolerance. See optim for details.
nlm.gradtol, nlm.steptol	tolerance at which the scaled gradient is considered close enough to zero and minimum allowable relative step length. See nlm .
fit.methods	'CG', 'BFGS' or both. If both then CG is run first and then BFGS. See optim .
quick.fit	logical, if TRUE extensive nlm optimization method is ignored and only BFGS and CG methods are run.
trace	logical, if to trace model fitting.
transform.latent, transform.thresh	type of the transformation applied to the all latent or all threshold numerical variables. Possible values: <ul style="list-style-type: none"> • "none" - no transformation • "min" - subtract minimum from a variable • "scale_01" - transform variable to fit the range from 0 to 1 • "standardize" or "standardise" - subtract mean from a variable then divide it by its standard deviation • "standardize_trunc" or "standardise_trunc" - subtract minimum from a variable then divide it by its standard deviation

hopit*Generalized hierarchical ordered threshold models.*

Description

The ordered response data classifies a measure of interest into ordered categories collected during a survey. For example, if the dependent variable were a happiness rating, then a respondent typically answers a question like: “Taking all things together, would you say you are ... ?” and then selects from response options along the lines of: “very happy”, “pretty happy”, “not too happy”, “very unhappy” \insertCiteLiao2005hopit. Similarly if interviewees are asked to evaluate their health in general (e.g. “Would you say your health is ... ?”) they may choose among several categories, such as “very good”, “good”, “fair”, “bad”, and “very bad” \insertCiteKing2004,Jurges2007,Rebello2014hopit. In political sciences a respondent may be asked for an opinion about recent legislation (e.g. “Rate your feelings about the proposed legislation.”) and asked to choose among categories like: “strongly oppose”, “mildly oppose”, “indifferent”, “mildly support”, “strongly support” \insertCiteGreeneHensher2010hopit. It is easy to imagine other multi-level ordinal variables that might be used during a survey and to which the methodology described below could be applied to.

Practically, it is assumed that when responding to a survey question about their general happiness, health, feeling, attitude or other status, participants assess their true value of this unobserved continuous variable, and project it to a provided discrete scale. The thresholds that each individual uses to categorize their true status into a specific response option may be affected by the choice of a reference group, earlier life experiences, and cross-cultural differences in using scales, and thus, may differ across individuals depending on their gender, age, cultural background, education, and personality traits, among other factors.

From the reporting behavior modeling perspective, one of the main tasks is to compute this continuous estimate of individuals’ underlying, latent measure based on several specific characteristics of the considered response (e.g. health variables or happiness variables) and accounting also for variations in reporting across socio-demographic and cultural groups. More specifically, to build the latent, underlying measure a generalized hierarchical ordered threshold model is fitted, which regresses the reported status/attitude/feeling on two sets of independent variables \insertCiteBoes2006,Green2014hopit. When a dependent reported ordered variable is self-rated health status then the first set of variables - health variables - assesses individuals’ specific aspects of health, and might include chronic conditions, mobility level, difficulties with a range of daily activities, performance on grip strength test, anthropometric measures, lifestyle behaviors, etc. Using the second set of independent variables (threshold variables), the model also adjusts for the differences across socio-demographic and cultural groups like cultural background, gender, age, education, etc. \insertCiteKing2004,Jurges2007hopit.

Ordered threshold models are used to fit ordered categorical dependent variables. The generalized ordered threshold models \insertCiteTerza1985,Boes2006,Green2014hopit are an extension to the ordered threshold models \insertCiteMcKelvey1975hopit. In the latter models, the thresholds are constant, whereas generalized models allows thresholds to be dependent on covariates. \insertCiteGreeneHensher2010,Green2014;textualhopit pointed out that also thresholds must be ordered so that a model has a sense. This motivated Greene and coauthors to call this models *HOPIT*, which stands for hierarchical ordered probit models.

The fitted *hopit* model is used to analyse heterogeneity in reporting behavior. See [standardizeCoef](#), [latentIndex](#), [getCutPoints](#), and [getLevels](#).

Usage

```
hopit(latent.formula, thresh.formula = ~1, data, decreasing.levels,
      start = NULL, overdispersion = FALSE, design = list(),
      weights = NULL, link = c("probit", "logit"), control = list())
```

Arguments

<code>latent.formula</code>	formula used to model latent variable. It should not contain any threshold variable. To specify interactions between latent and threshold variables see details.
<code>thresh.formula</code>	formula used to model threshold variable. It should not contain any latent variable. To specify interactions between latent and threshold variables see details. Any dependent variable (left side of "~" in the formula) will be ignored.
<code>data</code>	a data frame including all modeled variables.
<code>decreasing.levels</code>	logical indicating if self-reported health classes are ordered in decreasing order.
<code>start</code>	a vector with starting coefficient values in the form <code>c(latent_parameters, threshold_lambdas, threshold_gammas, logTheta)</code> if the <code>overdispersion == TRUE</code> .
<code>overdispersion</code>	logical indicting if to fit additional parameter theta, which models a variance of the error term.
<code>design</code>	an optional survey design. Use svydesign function to specify the design. The design cannot be specified together with parameter <code>weights</code> .
<code>weights</code>	optional model weights. Use <code>design</code> to construct survey weights.
<code>link</code>	the link function. The possible values are "probit" (default) and "logit".
<code>control</code>	a list with control parameters. See hopit.control .

Details

The function fits generalaized hierarchical ordered threshold models.

`latent.formula` models latent variable. if the response variable is self-rated health then latent measure can depend on different health conditions and diseases (latent variables are

called health variables). Latent variables are modeled with parallel regression assumption. According to the assumption, coefficients, which describe the relationship between lowest and all higher response categories, are the same as those coefficients, which describe the relationship between another (e.g. adjacent) lowest and the remaining higher response categories. The predicted latent variable is modeled as a linear function of health variables and corresponding coefficients.

`thresh.formula` models threshold variable. The thresholds (cut points, `alpha`) are modeled by threshold variables `gamma` and intercepts `lambda`. It is assumed that they model contextual characteristics of the respondent (e.g. country, gender, age, etc.). Threshold variables are modeled without parallel regression assumption, thus each threshold is modeled by a variable independently \insertCiteBoes2006,Green2014hopit. `hopit()` function uses parametrization of thresholds proposed by \insertCiteJurges2007;textualhopit.

`decreasing.levels` it is the logical that determines the ordering of levels of the categorical response variable. It is always good to check first the ordering of the levels before starting (see example 1)

It is possible to model interactions, including interactions between latent and threshold variables. Interactions added to the latent formula models only the latent measure and interactions modeled in threshold formula models only thresholds. The general rule for modeling any kind of interactions is to use `"*"` to specify interactions within latent (or threshold) formula and to use `':'` to specify interactions between latent and threshold variables. In the latter case the main effects of an interaction must be also specified, i.e. main latent effects must be specified in the latent formula and main threshold effect must be specified in the threshold formula. See also Example 3 below.

For more details please see the package vignette: "introduction_to_hopit".

Value

a `hopit` object used by other functions and methods. The object is a list with following components:

<code>control</code>	a list with control parameters. See hopit.control .
<code>link</code>	the used link function.
<code>hasdisp</code>	logical, was overdispersion modeled?
<code>use.weights</code>	logical indicating if any weights were used.
<code>weights</code>	vector with model weights.
<code>latent.formula</code>	used latent formula. It is updated by cross-interactions if <code>crossinter.formula</code> is delivered.
<code>latent.mm</code>	latent model matrix.
<code>latent.terms</code>	used latent variables and their interactions.
<code>cross.inter.latent</code>	part of the latent formula modeling cross-interactions in the latent model
<code>thresh.formula</code>	used threshold formula.

<code>thresh.mm</code>	threshold model matrix.
<code>thresh.extd</code>	threshold extended model matrix.
<code>thresh.terms</code>	used threshold variables and their interactions.
<code>cross.inter.thresh</code>	part of the threshold formula modeling cross-interactions in the threshold model
<code>thresh.no.cov</code>	logical, are gamma parameters present?
<code>parcount</code>	3-element vector with number of parameters for latent variable (beta), threshold intercept (lambda), and threshold covariates (gamma).
<code>coef</code>	a vector with coefficients.
<code>coef.ls</code>	coefficients as a list.
<code>start</code>	vector with starting values of coefficients.
<code>alpha</code>	estimated individual-specific thresholds.
<code>y_i</code>	the response variable.
<code>y_latent_i</code>	predicted latent measure.
<code>Ey_i</code>	predicted categorical response.
<code>J</code>	the number of response levels.
<code>N</code>	the number of observations.
<code>deviance</code>	deviance.
<code>LL</code>	log likelihood.
<code>AIC</code>	AIC for models without survey design.
<code>vcov</code>	variance-covariance matrix.
<code>vcov.basic</code>	variance-covariance matrix ignoring survey design.
<code>hessian</code>	a Hessian matrix.
<code>estfun</code>	gradient (vector of partial derivatives) of the log likelihood function at estimated coefficient values.
<code>YYY1, YYY2, YY3</code>	internal objects used for calculation of gradient and Hessian functions.

round(t(rbind(coef(model5b),
  coef(model5c),
  coef(model5d),
  coef(model5e),
  coef(model5f))),4)

## End(Not run)

```

latentIndex

Calculate latent index

Description

Calculate latent index from the fitted model. Latent index is a standardized latent measure, it takes values from 0 to 1, where zero is prescribed to the worse predicted state (maximal observed value for the latent measure) and 1 is prescribed to the best predicted health (minimal observed value for the latent measure).

Usage

```
latentIndex(model, decreasing.levels = TRUE, subset = NULL,
  plotf = FALSE, response = c("data", "fitted", "Jurges"),
  ylab = "Latent index", ...)
```

```
healthIndex(model, decreasing.levels = TRUE, subset = NULL,
  plotf = FALSE, response = c("data", "fitted", "Jurges"),
  ylab = "Latent index", ...)
```

Arguments

model a fitted hopit model.

decreasing.levels logical indicating if self-reported (e.g. health) classes are ordered in decreasing order.

<code>subset</code>	an optional vector specifying a subset of observations.
<code>plotf</code>	logical indicating if to plot summary figure.
<code>response</code>	X axis plotting option, choose 'data' for raw responses and 'fitted' for model reclassified responses
<code>ylab</code>	a label of y axis.
<code>...</code>	further parameters passed to the plot function.

Value

a vector with latent index for each individual.

```

percentile_CI	<i>Calculating confidence intervals of bootstrapped function using percentile method</i>
---------------	--

Description

Calculating confidence intervals of bootstrapped function using percentile method

Usage

```
percentile_CI(boot, alpha = 0.05, bounds = c("both", "lo", "up"))
```

Arguments

boot	a matrix or list of vectors with bootstrapped elements. If a list then each element of the list is one replication.
alpha	significance level.
bounds	one of "both", "lo", "up".

```

standardizeCoef	<i>Standardization of coefficients</i>
-----------------	--

Description

Calculate standardized coefficients (e.g. disability weights for health variables) using the predicted latent measure obtained from the model.

In the self-rated health example the standardized coefficients are called disability weights \insertCiteJurges2007;textualhopit and are calculated for each health variable to provide information about the impact of a specific health measure on the latent index (see [latentIndex](#)). The disability weight for a health variable is equal to the ratio of corresponding health coefficient and the difference between the lowest and highest values of predicted latent health. In other words, disability weight reduces latent index by some given amount or percentage (i.e. of every individual is reduced by the same amount if heart attack or other heart problems are present)\insertCiteJurges2007;textualhopit.

Usage

```
standardizeCoef(model, ordered = TRUE, plotf = FALSE,
  plotpval = FALSE, mar = c(15, 4, 1, 1), oma = c(0, 0, 0, 0),
  YLab = "Disability weight", YLab.cex = 1.1, namesf = identity, ...)

standardiseCoef(model, ordered = TRUE, plotf = FALSE,
  plotpval = FALSE, mar = c(15, 4, 1, 1), oma = c(0, 0, 0, 0),
  YLab = "Disability weight", YLab.cex = 1.1, namesf = identity, ...)

disabilityWeights(model, ordered = TRUE, plotf = FALSE,
  plotpval = FALSE, mar = c(15, 4, 1, 1), oma = c(0, 0, 0, 0),
  YLab = "Disability weight", YLab.cex = 1.1, namesf = identity, ...)
```

Arguments

model	a fitted hopit model.
ordered	logical indicating if to order the disability weights.
plotf	logical indicating if to plot results.
plotpval	logical indicating if to plot p-values.
mar, oma	see par .
YLab, YLab.cex	label and cex of y axis.
namesf	a vector of names of coefficients or one argument function that modifies names of coefficients.
...	arguments passed to boxplot .

Value

a vector with standardized coefficients.

svy.varcoef.hopit

Calculation of variance-covariance matrix for specified survey design (experimental function)

Description

This is a modification of `survey:::svy.varcoef`. In the original approach `estfun` is calculated from `glm`'s working residuals:

```
estfun <- model.matrix(glm.object) * resid(glm.object, "working") * glm.object$weights
```

In the `hopit` package `estfun` is directly calculated as a gradient (vector of partial derivatives) of log likelihood function.

Usage

```
svy.varcoef.hopit(Ainv, estfun, design)
```

Arguments

<code>Ainv</code>	a variance-covariance matrix.
<code>estfun</code>	LL gradient function.
<code>design</code>	a <code>survey.design</code> object.

Details

Based on the `survey v3.35` package.
