

# Test of hopit

January 20, 2019

---

anova.hopit

*Likelihood Ratio Test Tables*

---

## Description

Compute likelihood ratio test for two or more hopit objects.

## Usage

```
## S3 method for class 'hopit'  
anova(object, ..., method = c("sequential", "with.most.complex", 'with.least.complex'),  
direction = c("decreasing", "increasing"))
```

## Arguments

object	an object containing the results returned by a hopit.
...	additional objects of the same type.
method	the method of model comparison. Choose "sequential" for 1-2, 2-3, 3-4, ... comparisons or "with.most.complex" for 1-2, 1-3, 1-4, ... comparisons, where 1 is the most complex model.
direction	determine if complexity of listed models is "increasing" or "decreasing" (default).

## Value

a vector or a matrix with results of the test(s).

## Author(s)

Maciej J. Danko

## See Also

**Examples**

```

# DATA
data(healthsurvey)

# the order of response levels is decreasing (from the best health to the worst health)
levels(healthsurvey$health)

# Example 1 -----

# fitting two nested models
model1 <- hopit(latent.formula = health ~ hypertenssion + high_cholesterol +
  heart_atack_or_stroke + poor_mobility + very_poor_grip +
  depression + respiratory_problems +
  IADL_problems + obese + diabetes + other_diseases,
  thresh.formula = ~ sex + ageclass + country,
  decreasing.levels = TRUE,
  control = list(trace = FALSE),
  data = healthsurvey)

# model with interaction between hypertenssion and high_cholesterol
model2 <- hopit(latent.formula = health ~ hypertenssion * high_cholesterol +
  heart_atack_or_stroke + poor_mobility + very_poor_grip +
  depression + respiratory_problems +
  IADL_problems + obese + diabetes + other_diseases,
  thresh.formula = ~ sex + ageclass + country,
  decreasing.levels = TRUE,
  control = list(trace = FALSE),
  data = healthsurvey)

# Likelihood ratio test
lrt1 <- anova(model1, model2)
lrt1

# print results in shorter form
print(lrt1, short = TRUE)

# equivalently
lrt.hopit(model2, model1)

# Example 2 -----

# fitting additional nested models
model3 <- hopit(latent.formula = health ~ hypertenssion * high_cholesterol +
  heart_atack_or_stroke + poor_mobility + very_poor_grip +
  depression + respiratory_problems +
  IADL_problems + obese * diabetes + other_diseases,
  thresh.formula = ~ sex + ageclass + country,
  decreasing.levels = TRUE,
  control = list(trace = FALSE),
  data = healthsurvey)

model4 <- hopit(latent.formula = health ~ hypertenssion * high_cholesterol +

```

```

        heart_attack_or_stroke + poor_mobility + very_poor_grip +
        depression + respiratory_problems +
        IADL_problems + obese * diabetes + other_diseases,
thresh.formula = ~ sex * ageclass + country,
decreasing.levels = TRUE,
control = list(trace = FALSE),
data = healthsurvey)

# sequential likelihood ratio tests
# model complexity increases so direction = "increasing"
anova(model1, model2, model3, model4,
       direction = "increasing", method = "sequential")

# likelihood ratio tests of the most complex model with the rest
anova(model1, model2, model3, model4,
       direction = "increasing", method = "with.most.complex")

# likelihood ratio tests of the least complex model with the rest
anova(model1, model2, model3, model4,
       direction = "increasing", method = "with.least.complex")

```

boot\_hopit\_CI

*Calculating Confidence Intervals using percentile method***Description**

Calculating Confidence Intervals using percentile method

**Usage**

```
boot_hopit_CI(boot, alpha = 0.05, bounds = c("both", "lo", "up"))
```

**Arguments**

boot	boot object calculated by <code>boot_hopit</code> .
alpha	significance level.
bounds	one of "both", "lo", "up".

**Author(s)**

Maciej J. Danko

---

boot_hopit	<i>Bootstraping hopit model</i>
------------	---------------------------------

---

### Description

Bootstraping hopit model

### Usage

```
boot_hopit(model, data, func, nboot = 500, unlist = TRUE, ...)
```

### Arguments

model	a fitted Hopit model.
data	data used to fit the model.
func	function to be bootstrapped of the form func(model, data, ...).
nboot	number of bootstrap replicates.
unlist	logical indicting if to unlist boot object.
...	other parameters passed to the func.

getCutPoints	<i>Calcualte threshold cut-points using Jorges' method</i>
--------------	--

---

### Description

Calcualte threshold cut-points using Jorges' method.

### Usage

```
getCutPoints(model, subset = NULL, plotf = TRUE, mar = c(4, 4, 1, 1),
  oma = c(0, 0, 0, 0), XLab = "Health index", XLab.cex = 1.1,
  YLab = "Counts", YLab.cex = 1.1, decreasing.levels = TRUE,
  group.labels.type = c("middle", "border", "none"))
```

**Arguments**

**model** a fitted `hopit` model.  
**subset** an optional vector specifying a subset of observations.  
**plotf** logical indicating if to plot the results.  
**mar, oma** see [par](#).  
**XLab, XLab.cex** label and size of the label for x axis.  
**YLab, YLab.cex** label and size of the label for y axis.  
**decreasing.levels** logical indicating if self-reported health classes are ordered in decreasing order.  
**group.labels.type** position of the legend. One of `middel`, `border`, or `none`.

**Value**

a list with following components:

**cutpoints** cutpoints for adjusted categorical response levels with corresponding percentiles of latent index.  
**adjusted.levels** adjusted categorical response levels for each individual.

**Author(s)**

Maciej J. Danko

**References**

**Examples**

```

# DATA
data(healthsurvey)

# the order of response levels is decreasing (from the best health to the worst health)
levels(healthsurvey$health)

# Example 1 -----

# fitting a model
model1 <- hopit(latent.formula = health ~ hypertenssion + high_cholesterol +
  heart_atack_or_stroke + poor_mobility + very_poor_grip +
  depression + respiratory_problems +
  IADL_problems + obese + diabetes + other_diseases,
  thresh.formula = ~ sex + ageclass + country,
```

```

        decreasing.levels = TRUE,
        control = list(trace = FALSE),
        data = healthsurvey)

# Health index cut-points
z <- getCutPoints(model = model1)
z$cutpoints

# Adjusted health levels for individuals: Jorges method
rev(table(z$adjusted.levels))

# Original health levels for individuals
table(model1$y_i)

# Adjusted health levels for individuals: Estimated model thresholds
table(model1$Ey_i)

```

---

getLevels

Summarize adjusted and original response levels.

---

## Description

Summarize adjusted and original response levels

## Usage

```

getLevels(model, formula = model$thresh.formula,
  data = environment(model$thresh.formula), decreasing.levels = TRUE,
  sort.flag = FALSE, plotf = TRUE, sep = "_", mar = c(7, 2, 1.5, 0.5),
  oma = c(0, 3, 0, 0), YLab = "Fraction [%]", YLab.cex = 1.1,
  legbg = adjustcolor("white", alpha.f = 0.4), legbty = "o")

```

## Arguments

model	a fitted hopit model.
formula	a formula containing the grouping variables. It is by default set to threshold formula.
data	data used to fit the model.
decreasing.levels	logical indicating if self-reported health classes are ordered in increasing order.
sort.flag	logical indicating if to sort the levels.
plotf	logical indicating if to plot the results.
sep	separator for levels names.
mar, oma	see <a href="#">par</a> .
YLab, YLab.cex	label and size of the label for y axis.
legbg	legend background color. See bg parameter in <a href="#">legend</a> .
legbty	legend box type. See bty parameter in <a href="#">legend</a> .

**Value**

a list with following components:

original	frequencies of original response levels for selected groups/categories.
adjusted	frequencies of adusted response levels (Jurges 2007 method) for selected groups/categories.
N.original	numbers of original response levels for selected groups/categories.
N.adjusted	numbers of adusted response levels (Jurges 2007 method) for selected groups/categories.
categories	selected groups/categories usedin summary.
tab	original vs. adjusted contingency table.
mat	a matrix with columns: grouping variables, original response levels, adjusted response levels. Each row corresponds to a single individual from the data used to fit the model.

healthsurvey	<i>Artificially generated health survey data</i>
--------------	--

---

**Description**

A dataset containing artificially generated survey data

**Usage**

healthsurvey

**Format**

A data frame with 10000 rows and 11 variables:

**ID** personal identification number

**health** reported health, 5 levels

**diabetes** has diabetes? Yes or No

**obese** has obese? Yes or No

**IADL\_problems** problems in Instrumental Activities of Daily Living? Yes or No

**hypertension** has hypertension? Yes or No

**high\_cholesterol** has high cholesterol? Yes or No

**respiratory\_problems** has respirator problems? Yes or No

**heart\_attack\_or\_stroke** had stroke or heart attack? Yes or No

**poor\_mobility** has poor mobility? Yes or No  
**very\_poor\_grip** Cannot perform grip strength? Yes or No  
**depression** has depression? Yes or No  
**other\_diseases** has other diseases? Yes or No  
**sex** sex/gender: woman or man  
**ageclass** categorized age: [50,60), [60,70), [70,80), [80,120)  
**education** two levels of education: primary or lower and secondary or higher  
**country** country: X, Y, or Z  
**csw** cross-sectional survey weights  
**psu** primary statistical unit  
**ssu** secondary statistical unit

## Source

Data was randomly generated using probabilities of occurrence of particular combination of diseases, conditions, sex, age, education, reported health, etc. The structure of the data and some probabilities were inspired by WAVE1 SHARE database (DOIs: 10.6103/SHARE.w1.600), see Börsch-Supan et al for methodological details (Börsch-Supan et al. 2013).

The SHARE data collection has been primarily funded by the European Commission through FP5 (QLK6-CT-2001-00360), FP6 (SHARE-I3: RII-CT-2006-062193, COMPARE: CIT5-CT-2005-028857, SHARELIFE: CIT4-CT-2006-028812) and FP7 (SHARE-PREP: N°211909, SHARE-LEAP: N°227822, SHARE M4: N°261982). Additional funding from the German Ministry of Education and Research, the Max Planck Society for the Advancement of Science, the U.S. National Institute on Aging (U01\_AG09740-13S2, P01\_AG005842, P01\_AG08291, P30\_AG12815, R21\_AG025169, Y1-AG-4553-01, IAG\_BSR06-11, OGHA\_04-064, HHSN271201300071C) and from various national funding sources is gratefully acknowledged (see [www.share-project.org](http://www.share-project.org)).

None of the records represent any true record/individual of SHARE database

hopit.control

*Auxiliary for controlling hopit fitting*

---

## Description

Auxiliary function for controlling hopit fitting. Use this function to set control parameters of the [hopit](#) and other related functions.

**Usage**

```
hopit.control(grad.eps = 3e-05, bgfs.maxit = 10000, cg.maxit = 10000,
  nlm.maxit = 150, bgfs.reltol = 5e-10, cg.reltol = 5e-10,
  nlm.gradtol = 1e-07, nlm.steptol = 1e-07, fit.methods = c("CG", "BFGS"),
  quick.fit = TRUE, trace = TRUE, thresh.start = -Inf,
  thresh.1.exp = FALSE, LL_out_val = -Inf)
```

**Arguments**

`grad.eps`           epsilon for numerical hessian function.

`bgfs.maxit`, `cg.maxit`, `nlm.maxit`           the maximum number of iterations. See [optim](#) and [nlm](#) for details.

`bgfs.reltol`, `cg.reltol`           relative convergence tolerance. See [optim](#) for details.

`nlm.gradtol`, `nlm.steptol`           tolerance at which the scaled gradient is considered close enough to zero and minimum allowable relative step length. See [nlm](#).

`fit.methods`       either 'CG' or 'BFGS'. See [optim](#).

`quick.fit`       logical, if TRUE extensive nlm optimization method is ignored and only BFGS and CG methods are run.

`trace`           logical, if to trace model fitting.

`LL_out_val`, `thresh.1.exp`, `thresh.start`   internal parameters under developement, do not change.

hopit

*Generelaized hierarchical ordered threshold models.*

---

**Description**

The ordered response data classifies a measure of interest into ordered categories collected during a survey. If the dependent variable is a happiness then a respondent typically answers a question: "Taking all things together, would you say you are ...? " and have some response options e.g. "very happy", "pretty happy", "not too happy", "very unhappy" \insertCiteLiao2005hopit. Similarly if interviewees are asked to evaluate their health in general (e.g. "Would you say your health is ...?") they may choose among several categories, e.g. very good, good, fair, bad, and very bad \insertCiteKing2004,Jurges2007,Rebello2014hopit. In political sciences a respondent may be asked for an opinion about recent legislation (e.g. "Rate your feelings about the proposed legislation") and

asked to choose among several categories "strongly oppose", "mildly oppose", "indifferent", "mildly support", "strongly support" \insertCiteGreeneHensher2010hopit. It is easy to imagine other multi-level ordinal variables that might be used during the survey and to which methodology described below could be applied with.

Practically, it is assumed that when responding to a survey question about their general happiness, health, feeling, attitude or other status, participants assess their true value of this unobserved continuous variable, and project it to a provided discrete scale. The thresholds that each individual uses to categorize their true status into a specific response option may be affected by the choice of a reference group, earlier life experiences, and cross-cultural differences in using scales, and thus, may differ across individuals depending on their gender, age, cultural background, education, and personality traits, among other factors.

From the reporting-styles modeling perspective, one of the main tasks is to compute this continuous estimate of individuals' underlying, latent measure based on several specific characteristics of the considered response (e.g. health variables or happiness variables) and accounting also for variations in reporting across socio-demographic and cultural groups. More specifically, to build the latent, underlying measure a generalized hierarchical ordered threshold model is fitted, which regresses the reported status/attitude/feeling on two sets of independent variables \insertCiteBoes2006,Green2014hopit. When a dependent reported ordered variable is self-rated health status then the first set of variables (health variables) assesses individuals' specific aspects of health, and might include chronic conditions, mobility level, difficulties with a range of daily activities, performance on grip strength test, anthropometric measures, lifestyle behaviors, etc. Using the second set of independent variables (threshold variables), the model also adjusts for the differences across socio-demographic and cultural groups like cultural background, gender, age, education, etc. \insertCiteKing2004,Jurges2007hopit.

Ordered threshold models are used to fit ordered categorical dependent variables. The generalized ordered threshold models \insertCiteTerza1985,Boes2006,Green2014hopit are an extension to the ordered threshold models \insertCiteMcKelvey1975hopit. In the latter models the thresholds are constant, whereas generalized models allows thresholds to be dependent on covariates. \insertCiteGreeneHensher2010,Green2014;textualhopit pointed out that also thresholds must be ordered so that a model has a sense. This motivated Greene and coauthors to call this models *HOPIT*, which stands for hierarchical ordered probit models.

The fitted *hopit* model is used to analyse reporting styles. See [standardizeCoef](#), [latentIndex](#), [getCutPoints](#), and [getLevels](#).

## Usage

```
hopit(latent.formula, thresh.formula = ~1, strata.formula = ~1, data,
      decreasing.levels, start = NULL, overdispersion = FALSE,
      design = list(), weights = NULL, link = c("probit", "logit"),
      control = list())
```

## Arguments

`latent.formula` formula used to model latent variable.

<code>thresh.formula</code>	formula used to model threshold variable. Any dependent variable (left side of "~") will be ignored.
<code>strata.formula</code>	formula used to model interactions between threshold and latent variables. Each term in this formula will be interacted with all latent variables then and added to the <code>latent.formula</code> . Each term in this formula will be also added to <code>thresh.formula</code> . Any dependent variable (left side of "~") will be ignored.
<code>data</code>	a data frame including all modeled variables.
<code>decreasing.levels</code>	logical indicating if self-reported health classes are ordered in decreasing order.
<code>start</code>	a vector with starting coefficient values in the form <code>c(latent_parameters, threshold_lambdas, thresh_</code>
<code>overdispersion</code>	logical indicating if to fit additional parameter theta modeling a variance of the error term.
<code>design</code>	an optional survey design. Use <a href="#">svydesign</a> function to specify the design. The design cannot be specified together with parameter weights.
<code>weights</code>	an optional weights. Use <code>design</code> to construct survey weights.
<code>link</code>	the link function. The possible values are "probit" (default) and "logit".
<code>control</code>	a list with control parameters. See <a href="#">hopit.control</a> .

## Details

The function fits generalized hierarchical ordered threshold models.

`latent.formula` models latent variable. if the response variable is self-rated health then latent measure can depend on different health conditions and diseases (latent variables are called health variables). Latent variables are modeled with parallel regression assumption. According to the assumption, coefficients, which describe the relationship between lowest and all higher response categories, are the same as those coefficients, which describe the relationship between another (e.g. adjacent) lowest and the remaining higher response categories. The predicted latent variable is modeled as a linear function of health variables and corresponding coefficients.

`thresh.formula` models threshold variable. The thresholds (cut points, alpha) are modeled by threshold variables gamma and intercepts lambda. It is assumed that they model contextual characteristics of the respondent (e.g. country, gender, age, etc. ). Threshold variables are modeled without parallel regression assumption, thus each threshold is modeled by a variable independently \insertCiteBoes2006,Green2014hopit. `hopit()` function uses parametrization of thresholds proposed by \insertCiteJorgensen2007;textualhopit.

`decreasing.levels` it is the logical that determines the ordering of levels of the categorical response variable. It is always good to check first the ordering of the levels before starting (see example 1)

## Value

a `hopit` object used by other functions and methods. The object is a list with following components:

<code>control</code>	a list with control parameters. See <a href="#">hopit.control</a> .
<code>link</code>	used link function.
<code>hasdisp</code>	logical, was overdispersion modeled?
<code>latent.formula</code>	used latent formula.
<code>latent.mm</code>	latent model matrix.
<code>latent.terms</code>	used latent variables.
<code>thresh.formula</code>	used threshold formula.
<code>thresh.mm</code>	threshold model matrix.
<code>thresh.extd</code>	threshold extended model matrix.
<code>thresh.terms</code>	used threshold variables.
<code>thresh.no.cov</code>	logical, are gamma parameters present?
<code>parcount</code>	3-element vector with number of parameters for latent variable (beta), threshold intercept (lambda), and threshold covariates (gamma).
<code>coef</code>	vector with coefficients.
<code>coef.ls</code>	coefficients as a list.
<code>start</code>	vector with starting values of coefficients.
<code>alpha</code>	estimated individual-specific thresholds.
<code>y_i</code>	response variable.
<code>y_latent_i</code>	predicted latent measure.
<code>Ey_i</code>	predicted categorical response.
<code>J</code>	number of response levels.
<code>N</code>	number of observations.
<code>deviance</code>	deviance.
<code>LL</code>	log likelihood.
<code>AIC</code>	AIC for models without survey design.
<code>vcov</code>	variance-covariance matrix.
<code>hessian</code>	hessian matrix.
<code>estfun</code>	gradient of the log likelihood function at estimated coefficient values.
<code>YYY1, YYY2, YYY3</code>	internal objects used for calculation of gradient and hessian functions.
<code>use.weights, vcov.basic, glm.start, glm.start.ls</code>	other internal objects.

**Examples**

```
# DATA
data(healthsurvey)

# first determine the order of the dependent variable
levels(healthsurvey$health)

# Example 1 -----

# the order is decreasing (from the best health to the worst health)
# so we set: decreasing.levels = TRUE
# fitting the model:
model1 <- hopit(latent.formula = health ~ hypertenssion + high_cholesterol +
  heart_atack_or_stroke + poor_mobility + very_poor_grip +
  depression + respiratory_problems +
  IADL_problems + obese + diabetes + other_diseases,
  thresh.formula = ~ sex + ageclass + country,
  decreasing.levels = TRUE,
  control = list(trace = FALSE),
  data = healthsurvey)

# summarize the fit:
summary(model1)

# extract parameters in a form of list
cm1 <- coef(model1, aslist = TRUE)

# names of returned coefficients
names(cm1)

# extracting latent health coefficients
cm1$latent.params

# Checking the fit
profile(model1)

# Example 2 -----

# incorporating survey design
design <- svydesign(ids = ~ country + psu, weights = healthsurvey$csw,
  data = healthsurvey)

model2 <- hopit(latent.formula = health ~ hypertenssion + high_cholesterol +
  heart_atack_or_stroke + poor_mobility +
```

```

        very_poor_grip + depression + respiratory_problems +
        IADL_problems + obese + diabetes + other_diseases,
thresh.formula = ~ sex + ageclass + country,
decreasing.levels = TRUE,
design = design,
control = list(trace = FALSE),
data = healthsurvey)

# compare latent variables
cbind('No survey design' = coef(model1, aslist = TRUE)$latent.par,
'Has survey design' = coef(model2, aslist = TRUE)$latent.par)

# Example 3 -----

# using strata.formula
model3 <- hopit(latent.formula = health ~ hypertenssion + high_cholesterol +
        heart_atack_or_stroke + poor_mobility + very_poor_grip +
        depression + respiratory_problems +

---

latentIndex	<i>Calculate latent index</i>
-------------	-------------------------------

---

### Description

Calculate latent index from the latent variable. It takes values from 0 to 1, where zero is prescribed to the worse predicted state (maximal observed value for the latent variable) and 1 is prescribed to the best predicted health (minimal observed value for the latent variable).

### Usage

```
latentIndex(model, decreasing.levels = TRUE, subset = NULL, plotf = FALSE,
  response = c("data", "fitted", "Jurges"), ylab = "Latent index", ...)
```

```
healthIndex(model, decreasing.levels = TRUE, subset = NULL, plotf = FALSE,
  response = c("data", "fitted", "Jurges"), ylab = "Latent index", ...)
```

### Arguments

model	a fitted hopit model.
decreasing.levels	logical indicating if self-reported (e.g. health) classes are ordered in decreasing order.
subset	an optional vector specifying a subset of observations.
plotf	logical indicating if to plot summary figure.
response	X axis plotting option, choose 'data' for raw responses and 'fitted' for model reclassified responses
ylab	a label of y axis.
...	further parameters passed to the <a href="#">plot</a> function.

### Value

a vector with latent index for each individual.

```

---

standardizeCoef

*Standardization of coefficients*

---

**Description**

Calculate standardized coefficients - disability weights computed as the latent coefficients from the generalised ordered probit model divided by the maximum possible range of its linear prediction. The range is calculated as difference between maximum and minimum possible value of the latent variable given estimated parameters.

**Usage**

```
standardizeCoef(model, ordered = TRUE, plotf = FALSE, plotpval = FALSE,
  mar = c(15, 4, 1, 1), oma = c(0, 0, 0, 0), YLab = "Disability weight",
  YLab.cex = 1.1, namesf = identity, ...)

standardiseCoef(model, ordered = TRUE, plotf = FALSE, plotpval = FALSE,
  mar = c(15, 4, 1, 1), oma = c(0, 0, 0, 0), YLab = "Disability weight",
  YLab.cex = 1.1, namesf = identity, ...)

disabilityWeights(model, ordered = TRUE, plotf = FALSE, plotpval = FALSE,
  mar = c(15, 4, 1, 1), oma = c(0, 0, 0, 0), YLab = "Disability weight",
  YLab.cex = 1.1, namesf = identity, ...)
```

**Arguments**

<code>model</code>	a fitted <code>hopit</code> model.
<code>ordered</code>	logical indicating if to order the disability weights.
<code>plotf</code>	logical indicating if to plot results.
<code>plotpval</code>	logical indicating if to plot p-values.
<code>mar</code> , <code>oma</code>	see <a href="#">par</a> .
<code>YLab</code> , <code>YLab.cex</code>	label and size of the label for y axis.
<code>namesf</code>	vector of names of coefficients or one argument function that modifies names of coefficients.
<code>...</code>	arguments passed to <a href="#">boxplot</a> .

**Value**

a vector with standardized coefficients.
